(57) **ABSTRACT**
System and methods for managing one or more unmanned aerial vehicles. The system can include an unmanned aerial vehicle, a landing station for the unmanned aerial vehicle, and a loading station for receiving a package and unmanned aerial vehicle. The unmanned aerial vehicle can be configured to: (i) determine a first confidence level for landing on the landing station, (ii) travel, based on the first confidence level, to the landing station, and (iii) determine a second confidence level for delivering the package to a delivery destination. The loading station can be configured to: (i) receive the second confidence level to deliver the package to the delivery destination from the unmanned aerial vehicle, and (ii) confirm, based on the second confidence level, the unmanned aerial vehicle is capable of delivering the package to the delivery destination.

SYSTEM AND METHOD FOR COORDINATING UNMANNED AERIAL VEHICLES FOR DELIVERY OF ONE OR MORE PACKAGES

PRIORITY

The present application depends from U.S. Provisional Patent Application No. 62/624,752, filed Jan. 31, 2018, the contents of which are incorporated herein in their entirety.

BACKGROUND

1. Technical Field

The present disclosure generally relates to an unmanned vehicle station, and more specifically, systems and methods for coordinating the arrangement of one or more unmanned aerial vehicles for delivery of one or more packages, while confirming that they are able to deliver the package and loading them with them with the package.

2. Introduction

Unmanned aerial vehicles are becoming more common in everyday use, particularly by companies to deliver packages to customers. However, unmanned aerial vehicles are machines, and thus, pose many maintenance challenges and capability limitations. For instance, it is common for unmanned aerial vehicles to routinely need maintenance. Also, it is common for unmanned aerial vehicles to not be able to operate to their full capacity, therefore having limited capabilities. Therefore, a technical problems exists in how to determine which package may be paired with a particular unmanned aerial vehicle. Additional technical problems exist in how to autonomously determine any required maintenance on the unmanned aerial vehicles, and how to pair unmanned aerial vehicles with appropriate packages.

SUMMARY

Additional features and advantages of the disclosure will be set forth in the description which follows, and in part will be obvious from the description, or can be learned by practice of the herein disclosed principles. The features and advantages of the disclosure can be realized and obtained by means of the instruments and combinations particularly pointed out in the appended claims. These and other features of the disclosure will become more fully apparent from the following description and appended claims, or can be learned by the practice of the principles set forth herein.

In an embodiment of the present invention, a system for managing one or more unmanned aerial vehicles is provided, including: an unmanned aerial vehicle; a landing station for the unmanned aerial vehicle to land thereon; and a loading station configured to receive a package and the unmanned aerial vehicle. The unmanned aerial vehicle is stationed a location away from the landing station and the loading station. The unmanned aerial vehicle is also in communication with the landing station and configured to: determine a first confidence level for landing on the landing station; travel, based on the first confidence level, to the landing station; and determine a second confidence level for delivering the package to a destination. The loading station is in communication with the unmanned aerial vehicle and configured to: receive the second confidence level to deliver the package to the destination from the unmanned aerial

2

vehicle; and confirm, based on the second confidence level, the unmanned aerial vehicle is capable of delivering the package to the destination.

In an embodiment of the present invention, a system for managing one or more unmanned aerial vehicles is provided, including: an unmanned aerial vehicle; a landing station for the unmanned aerial vehicle to land on; a maintenance station in communication with the landing station and configured to perform maintenance on the unmanned aerial vehicle; a loading station configured to receive the unmanned aerial vehicle from the landing station and to receive the package from the packaging system; and a packaging system in communication with the loading station and including a storage for storing a plurality of packages including the package.

The unmanned aerial vehicle can be configured to: determine a first confidence level for landing on the landing station, and travel, based on the first confidence level, to the landing station or the maintenance station. The loading station can be configured to: receive, from the landing station, the unmanned aerial vehicle; receive, from the packaging system, the package; determine a second confidence level for the unmanned aerial vehicle to deliver the package; select, based on the confidence level, the package for the unmanned aerial vehicle; and instruct, based on the second confidence level, to select and attach to the package for delivery to destination.

In an embodiment of the present invention, a method for managing one or more unmanned aerial vehicles can include: determining, at a landing station, a first confidence level of an unmanned aerial vehicle to land on the landing station; instructing, based on the first confidence level, the unmanned aerial vehicle to land on the landing station; determining, at the landing station, a second confidence level of the unmanned aerial vehicle for maintenance; transporting, based on the second confidence level, the unmanned aerial vehicle to the loading station; identifying, at the packaging system, a package for delivery; determining, at the packaging system, a third confidence level of the unmanned aerial vehicle for delivery of the package; transporting, based on the third confidence level, the package to the loading station; instructing, at the loading station, the unmanned aerial vehicle to select and attach to the package; transporting the unmanned aerial vehicle and the package to a launching station; and launching, at the launching station, the unmanned aerial vehicle and the package to the destination.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1, 10 and 11 illustrate exemplary systems that can manage one or more unmanned aerial vehicle for delivery of a package to a particular destination in accordance with embodiments of the present invention;

FIGS. 2-5 and 7-9 illustrate exemplary flowcharts describing communication between various components of the system illustrated in FIG. 1 in accordance with embodiments of the invention;

FIG. 6 illustrates of an exemplary loading station of the system depicted in FIG. 1 in accordance with embodiments of the invention;

FIG. 12 illustrates an exemplary method for arranging one or more unmanned aerial vehicle for delivery of a package to a particular destination in accordance with embodiments of the present invention; and

FIG. 13 illustrates a schematic diagram of an exemplary control server that can be utilized in accordance with embodiments of the present invention.

DETAILED DESCRIPTION

Various embodiments of the disclosure are described in detail below. While specific implementations are described, it should be understood that this is done for illustration purposes only. Other components and configurations may be used without parting from the spirit and scope of the disclosure. It is also important to note that any reference in the specification to “one embodiment,” “an embodiment” or “an alternative embodiment” means that a particular feature, structure or characteristic described in connection with the embodiment is included in at least one embodiment of the invention. As such, the recitation of “in one embodiment” and the like throughout the specification does not necessarily refer to the same embodiment.

The systems and methods disclosed herein are intended to arrange one or more unmanned aerial vehicles for the delivery of a package to a destination. Based on specific configurations, the various embodiments described herein can solve one or more of the technical problems described above. As will be discussed in more detail below, the unmanned aerial vehicles can have different capabilities which limit the packages they may deliver, and the packages may have different characteristics which limit the unmanned aerial vehicles that may deliver them. As such, to confirm that the unmanned aerial vehicles are capable to deliver one or more particular packages, the unmanned aerial vehicles can be assessed to confirm that do not need maintenance, are capable of delivering the particular package, informed of a delivery destination of the particular package, loaded with particular package, and/or launched with the particular package to the delivery destination.

Referring now to the figures, various embodiments of systems for coordinating one or more unmanned aerial vehicles for delivery of one or more packages to various locations and methods thereof will be described. Referring now to FIG. 1, an exemplary system 100 for coordinating the arrangements one or more unmanned aerial vehicles for delivery of a package to a destination is described. The system 100 can include one or more of a landing station 101, a maintenance station 102, a loading station 104, a packaging system 145, an identifying system 149, a launching station 105, and a central server 106. The communication between the landing station 101, the maintenance station 102, the loading station 104, the packing system 145, the identifying system 149, and the launching station 105 can be managed by the central server 106, as will be discussed in more detail below.

The system utilizes two respective confidence levels: first, the confidence that the unmanned aerial vehicle 107 can complete the mission; second, the confidence that the unmanned aerial vehicle 107 can succeed at the mission within needed business parameters, such as delivering a package within a given period of time. With respect to the first confidence level, that the unmanned aerial vehicle 107 can complete the mission, this confidence should approximate one hundred percent, the aeronautical standard for civilian operations. Both confidence levels taken together can provide an overall confidence that the unmanned aerial vehicle can complete its mission, e.g., delivery of the package within a commercially relevant amount of time.

A number of factors should be taken into account into one or both of the respective confidence levels: (1) Spatial

limitations, such as the dimensions of the landing zone and/or the range to the target; (2) Temporal limitations, such as a duration of a battery, the speed by which a drone can get to a target; (3) Material considerations, such as the size of the package or the carrying capacity of the UAV; (4) Environmental considerations, such as weather, wildlife, or traffic (land or air); (5) Communication considerations, such as dead zones or areas where communication is limited.

The landing station 101 can be in communication with one or more unmanned aerial vehicles 107. The unmanned aerial vehicle 107 can be located and stationed away from the landing station 101. As such, the landing station 101 can be in communication with the unmanned aerial vehicle 107 to determine if the unmanned aerial vehicle 107 can land at the landing station 101. To do so, the landing station 101 can request a level of confidence from the unmanned aerial vehicle 107 for landing on the landing station 101.

Upon such a request, the unmanned aerial vehicle 107 can determine its level of confidence in landing on the landing station 101. To determine its level of confidence, the unmanned aerial vehicle 107 can consider one or more characteristics of the unmanned aerial vehicle 107 and a size of the landing station. The characteristic of the unmanned aerial vehicle 107 can include one or more of a size, a fuel level, a battery level, and a maintenance status of the unmanned aerial vehicle 107. For example, to determine its level of confidence for landing on the landing station 101, the unmanned aerial vehicle can determine a current battery or fuel level of the unmanned aerial vehicle and a maintenance status of any other component of the unmanned aerial vehicle 107.

As such, if the unmanned aerial vehicle 107 determines its level of confidence meets a predetermined level of confidence for the unmanned aerial vehicle 107 to land on the landing station 101, the unmanned aerial vehicle 107 can land on the landing station 101. However, if the unmanned aerial vehicle 107 does not meet the predetermined level of confidence, the unmanned aerial vehicle 107 can return to a station from which it resides or another location (not illustrated). As such, the level of confidence for the unmanned aerial vehicle 107 to land on the landing station 101 can be within a predefined range of levels of confidence. According to an embodiment, the predefined range can be between -1 and +1. For example, the level of confidence can be intervals, such as “-1,” “0,” and “+1.” The level of confidence of “-1” can refer to the unmanned aerial vehicle 107 not being confident in landing on the landing station 101. The level of confidence of “0” can refer to the unmanned aerial vehicle 107 being somewhat confident in landing on the landing station. The level of confidence of “+1” can refer to the unmanned aerial vehicle 107 being confident it landing on the landing station. According to an embodiment, if the level of confidence for the unmanned aerial vehicle 107 to land on the landing station 101 is “+1,” it can proceed to, and land on, the landing station 101. Otherwise, if the level of confidence of the unmanned aerial vehicle 107 to land on the landing station 101 is “-1” or “0,” the unmanned aerial vehicle 107 can return to the station from which it resides (not illustrated). In other configurations, the confidence level can be a range, such as “30% confident in performing the task” or “90% likelihood of failure,” and the confidence requirements can require a threshold level be met. Such ranges and thresholds can be used for all instances of confidence scores/requirements as disclosed herein.

Thus, upon meeting the predetermined level of confidence, the landing station 101 can receive the level of confidence from the unmanned aerial vehicle 107. Thereaf-

5

ter, the landing station 101 can inform the central server 106 that the unmanned aerial vehicle 107 is capable of landing on the landing station 101. Along these lines, the central server 106 can indicate a time at which the unmanned aerial vehicle 107 can travel to the landing station 101. By doing so, the central server 106 can ensure that unmanned aerial vehicle 107 does not intersect with other unmanned aerial vehicles traveling to different landing stations.

Referring now to FIG. 2, an exemplary flowchart describing communication between various components of the system 100 for the unmanned aerial vehicle 107 to advance to the landing station 101 (each illustrated in FIG. 1) is illustrated. At step 108, the unmanned aerial vehicle 107 can connect to the central server. Thereafter, at step 109, the central server can determine if the unmanned aerial vehicle is clear for traveling to the landing station 101. Upon doing so, at step 110, the unmanned aerial vehicle can connect to the landing station for clearance to land. Subsequently, at step 111, the landing station can request a level of confidence of the unmanned aerial vehicle 107 for landing on the landing station. At step 112, the unmanned aerial vehicle can respond with a level of confidence of “-1,” “0,” or “+1.” Accordingly, as described in step 113, if the unmanned aerial vehicle responds with a level of confidence of “-1,” the landing station can send a signal to the central server that it is not confident in landing on the landing station. However, if the unmanned aerial vehicle responds with a level of confidence of “+1,” as described in step 114, the landing station can send a signal to the central server to confirm that all incoming and outgoing unmanned aerial vehicles are clear, as described in step 115. By doing so, as described in step 116, the landing station and the central server can together confirm that the unmanned aerial vehicle is clear for landing. Thereafter, at step 117, the unmanned aerial vehicle can land on the landing station.

Referring back to FIG. 1, when the unmanned aerial vehicle 107 lands on the landing station 101, the landing station 101 can determine whether the unmanned aerial vehicle 107 proceeds to the maintenance station 102 or the loading station 104. To do so, the landing station 101 can request, from the unmanned aerial vehicle 107, a level of confidence for maintenance of the unmanned aerial vehicle 107. As described above with respect to landing on the landing station 101, the unmanned aerial vehicle 107 can determine if its level of confidence for maintenance meets a predetermined level of confidence within a predefined range. The maintenance can relate to maintenance of any component of the unmanned aerial vehicle, including, but not limited to, energy, fuel, propellers, sensors, actuators, and communication modules. Along these lines, the maintenance performed on the unmanned aerial vehicle 107 can relate to delivery of a package to a delivery destination. For instance, the maintenance performed on the unmanned aerial vehicle 107 can be to permit delivery of the package to the delivery destination.

As such, if the unmanned aerial vehicle 107 meets the predetermined level of confidence, the unmanned aerial vehicle 107 can go to the loading station 104. Otherwise, the unmanned aerial vehicle 107 can go to the maintenance station 102. According to an embodiment, the predefined range can be between -1 and +1. For example, the level of confidence can be intervals, such as “-1,” “0,” and “+1.” The level of confidence of “-1” or “0” can refer to the unmanned aerial vehicle 107 needing maintenance. The level of confidence of “+1” can refer to the unmanned aerial vehicle 107 not needing maintenance.

6

Moreover, the landing station 101 can include one or more of a rotating swivel and a trap door. The rotating swivel can rotate and connect to either a first transportation mechanism 118 or a second transportation mechanism 119, as will be discussed in more detail below. In doing so, the rotating swivel can direct the unmanned aerial vehicle 107 towards either the first transportation mechanism 118 or the second transportation mechanism 119. As such, the unmanned aerial vehicle 107 can be instructed to land on the swivel of the landing station 101. As to the trap door, it can hold and/or maintain the unmanned aerial vehicle 107 in place until it is determined if it is going to the maintenance station 102 or the loading station 104. At such time, the trap door can permit the unmanned aerial vehicle 107 to proceed to the maintenance station 102 or the loading station 104.

To transport the unmanned aerial vehicle 107 to the maintenance station 102, the landing station 101 can be connected to the maintenance station 102 by a first transportation mechanism 118, and the landing station 101 can be connected to the loading station 104 by a second transportation mechanism 119. The first transportation mechanism 118 can transport the unmanned aerial vehicle 107 to the maintenance station 102, and the second transportation mechanism 119 can transport the unmanned aerial vehicle 107 to the loading station 104. The first transportation mechanism 118 and/or the second transportation mechanism 119 can include a conveyor belt or a plurality of rollers. As illustrated, the first transportation mechanism 118 and the second transportation mechanism 119 can each include a conveyor belt. Along these lines, the first transportation mechanism 118 can check one or more maintenance properties of the unmanned aerial vehicle 107. To do so, the first transportation mechanism 118 can include one or more sensors capable of detecting the maintenance properties of the unmanned aerial vehicle. The maintenance properties can relate to any component of the unmanned aerial vehicle 107, as mentioned above.

Upon arrival to the maintenance station 102, the maintenance station 102 can perform one or more servicing procedures on the unmanned aerial vehicle 107. The maintenance to the unmanned aerial vehicle 107 at the maintenance station 102 can be done by a robotic arm 151. The robotic arm 151 can be a track 268 extending from the maintenance station 102 to the identifying system 149. Although not illustrated, the maintenance to the unmanned aerial vehicle 107 at the maintenance station 102 can be done by an individual.

While the second transportation mechanism 119 transports the unmanned aerial vehicle 107 to the loading station 104, the second transportation mechanism 119 can check one or more capabilities of the unmanned aerial vehicle. To do so, the second transportation mechanism 119 can be able to identify the type of unmanned aerial vehicle 107 and determine its capabilities. The capabilities can include any property relating to operation of the unmanned aerial vehicle in transporting a package. For example, capabilities of the unmanned aerial vehicle can include a fly-time, a flying distance, a maximum miles per hour, a maximum size for package transportation, and a maximum weight for package transportation. As such, the capabilities can relate to one or more properties of the unmanned aerial vehicle in a current state.

Moreover, while the second transportation mechanism 119 transports the unmanned aerial vehicle 107 to the loading station 104, the second transportation mechanism can check a level of confidence for performing one or more capabilities. The level of confidence for the unmanned aerial

vehicle 107 for performing a capability can be a predetermined level. The predetermined level can reside within a predefined range. The predefined range can be the same as the predefined range discussed above with respect to the level of confidence for the unmanned aerial vehicle 107 for landing on the landing station 101. For example, the level of confidence for the unmanned aerial vehicle 107 for performing a capability can be -1 , 0 , or $+1$. As such, the level of confidence of -1 can relate to the unmanned aerial vehicle 107 not being confident in performing the capability. The level of confidence of 0 can relate to the unmanned aerial vehicle being confident in performing the capability. The level of confidence of $+1$ can relate to the unmanned aerial being confident in performing the capability.

Based on the level of confidence for performing the capability, the unmanned aerial vehicle 107 can send a signal to be matched with a particular package. For example, the unmanned aerial vehicle 107 can be matched with a particular package based on a degree of the level of confidence. For example, if the level of confidence of the unmanned aerial vehicle 107 for performing the capability is -1 , the unmanned aerial vehicle 107 can be deemed be able to be confident to meet 25% of the capability and an appropriate package is selected. If the level of confidence of the unmanned aerial vehicle 107 for performing the capability is 0 , the unmanned aerial vehicle 107 can be deemed be able to be confident to meet 50% of the capability and an appropriate package is selected. If the level of confidence of the unmanned aerial vehicle 107 for performing the capability is $+1$, the unmanned aerial vehicle 107 can be deemed be able to be confident to meet 100% of the capability and an appropriate package is selected. For example, if the unmanned aerial vehicle is capable of carrying 100 pounds but its level of confidence for performing this capability is -1 , the unmanned aerial vehicle will be deemed confidence to carry 25 pounds (e.g., 25% of 100 pounds).

Referring now to FIG. 3, an exemplary flowchart illustrating the communication between various components of the system 101 for determining maintenance of the unmanned aerial vehicle 107 (each shown in FIG. 1) is depicted. Starting at step 120, the landing station 101 can communicate with the unmanned aerial vehicle 107 to determine its confidence level for maintenance, for example, its confidence for fuel, battery, and mechanical maintenance. If the unmanned aerial vehicle 107 has a confidence level for maintenance of $+1$, then, as described at step 121, the landing station can send a signal to the central server that the unmanned aerial vehicle does not need maintenance and proceed to the second transportation mechanism for transportation to the loading pad. Thereafter, at step 122, the landing station can signal its rotating swivel to send the unmanned aerial vehicle to the loading pad. Upon doing so, at step 123, the rotating swivel can connect to the central server to inform it that the drone has been rotated and boarded the second transportation mechanism 119.

However, if the unmanned aerial vehicle has a confidence level for maintenance of -1 or 0 , then, as described at step 124, the landing station can send a signal to the central server that the unmanned aerial vehicle needs maintenance. Thereafter, at step 125, the landing station can signal its rotating swivel to send the drone to the maintenance pad. Upon doing so, at step 126, the rotating swivel can connect to the central server to inform that the unmanned aerial vehicle will be boarding the first transportation mechanism for transportation to the maintenance pad.

Referring now to FIG. 4, an exemplary flowchart illustrating communication between various components of the system 101 for determining appropriate transportation of the unmanned aerial vehicle 107 (each depicted in FIG. 1) is shown. Starting at step 127, once the unmanned aerial vehicle has boarded the first transportation mechanism or the second transportation mechanism, the first transportation mechanism and/or the second transportation mechanism can connect to the central server to notify where the unmanned aerial vehicle is going (i.e., the maintenance pad or loading pad). As shown in step 128, if the unmanned aerial vehicle does not need maintenance (e.g., fuel), the second mechanism can notify the central server that the unmanned aerial vehicle is headed toward the loading pad. At step 129, the central server can then confirm that the unmanned aerial vehicle is proceeding to the loading pad. At step 130, the unmanned aerial vehicle can ride the second transportation mechanism to the loading pad. While doing so, at step 131, the second transportation mechanism can check one or more capabilities of the unmanned aerial vehicle and notify the central server of such capabilities. At 132, the second transportation mechanism can check the confidence level of the unmanned aerial vehicle for performing up to its capabilities and notify the central server of its confidence level. Thereafter, at step 133, the second transportation mechanism can signal the central server that the unmanned aerial vehicle has reached the loading pad. At step 134, the loading pad can confirm that the unmanned aerial vehicle has reached the loading pad. Subsequently, at step 135, the central server can confirm that the loading pad may proceed in operating the loading pad, as will be discussed in more detail below.

However, if the unmanned aerial vehicle needs maintenance (e.g., fuel), at step 136, the first transportation mechanism can notify the central server that the unmanned aerial vehicle is headed towards the maintenance pad for maintenance (e.g., refueling). Thereafter, at step 137, the central server can confirm that the unmanned aerial vehicle may proceed to the maintenance pad. Subsequently, at step 138, the unmanned aerial vehicle can ride the first transportation mechanism to the maintenance pad. At step 139, while the first transportation mechanism carries the unmanned aerial vehicle to the maintenance pad, the first transportation mechanism can check one or more capabilities of the unmanned aerial vehicle and notify the central server of them. Thereafter, at step 140, while the first transportation mechanism carries the unmanned aerial vehicle to the maintenance pad, the first transportation mechanism can check a confidence level unmanned aerial level for maintenance and/or performing its capabilities, as described above.

Upon reaching the maintenance pad, at step 141, the first transportation mechanism can signal to the central server that the unmanned aerial vehicle has reached the maintenance pad. Also, at step 142, the maintenance pad can signal to the central server that the unmanned aerial vehicle has reached the maintenance pad. By doing so, at step 143, the central server can confirm that the maintenance pad may proceed and perform maintenance on the unmanned aerial vehicle. Accordingly, at step 144, the unmanned aerial vehicle is checked to determine the maintenance it needs.

Referring back to FIG. 1, the packaging system 145 can include a storage compartment 145 for storing one or more packages, and optionally, a placement mechanism 146 for placing the package on/in the storage compartment. The identifying system 149 can determine one or more properties of a package. The packaging system 149 and/or identifying system 149 can be located inside of a distribution center.

According to an embodiment, the packaging system **149** can be located inside of a distribution center, and the identifying system **149** can be located outside of a distribution center.

Along these lines, a transport mechanism **150** can transport a package from the storage compartment of the packaging system **145** to an identifying system **149** configured to identify one or more properties of the package. The placement mechanism **146** and/or the transport mechanism **150** can be a robotic arm. The robotic arm for the placement mechanism **146** and the transport mechanism **150** can move along separate tracks **147**, **148**. Moreover, the properties of the package that the identifying system **149** can include an identity, a size, a weight, dimensions, and/or a shape of the package. According to an embodiment, as illustrated, the identifying system **149** can be a weighing system configured to determine a weight of the package.

In operation, the packaging system **149** can be in communication with a computer (not illustrated). The computer may belong to distribution center and/or local store. Moreover, the computer can transmit one or more packages to be shipped and one or more capabilities of an unmanned aerial vehicle **107** to deliver the package. As such, the packaging system may receive a signal from the central server **106** via the computer to place a package on the identifying system **149**. According to an embodiment, the central server **106** can request a specific package based on one or more characteristics of the package and/or unmanned aerial vehicle. According to another package, the computer can select a specific package based on one or more characteristics of the package and/or unmanned aerial vehicle. For example, the central server **106** can request, or the computer can select, a package based on receipt of an order, a weight of the package, dimensions of the package, and/or shape of the package.

The packaging system **149** can also connect to the loading station **104** and/or unmanned aerial vehicle **107**. In doing so, the packaging system **149** can check the capabilities of one or more unmanned aerial vehicles on the loading pad to determine if the unmanned aerial vehicle at, or on its way, to the loading station **104** is compatible with the package. The packaging system **149** can also inform the unmanned aerial vehicle **107** and the central server **106** of the delivery destination of the unmanned aerial vehicle **107**.

Along these lines, the packaging system **145** can determine a confidence level for the unmanned aerial vehicle **107** to deliver the package, as discussed above, prior to transportation of the package to the identifying system **149**. The identifying system **149** can confirm such a confidence level for the unmanned aerial vehicle to delivery of the package to the loading station **104**. Alternatively, the identifying system **149**, and not the packaging system **145**, may determine a confidence level for the unmanned aerial vehicle prior to delivery of the package to the loading station **104**.

Moreover, upon the package being placed on the identifying system **149**, a third transportation mechanism **176** can transport the package from the identifying system **149** to the loading station **104**. Along these lines, the transportation mechanism can physically connect the weighing system **149** to the loading station **104**. The third transportation mechanism **176** can include a conveyor belt or a plurality of rollers.

Referring now to FIG. 5, an exemplary flowchart illustrating the communication between various components of the system **101** for determining selection and shipment of a package by the packaging system **145** (each shown in FIG. 1) is illustrated. At step **152**, the packaging system can determine what package needs to be delivered from a computer inside the distribution center. Thereafter, at step

153, the packaging system can notify the loading station and the central server, through the computer, of the package that needs to be delivered. Subsequently, at step **154**, the packaging system can read a time at which the package needs to be delivered, from the computer. Upon doing so, at step **155**, the packaging system can notify the loading station and the central server of such a time through the computer by, for example, comparing the package specification with the drone capabilities. At step **156**, the packaging system can check one or more capabilities required for an unmanned aerial vehicle to deliver the package from the computer. At step **157**, the packaging system can sync-up with the loading station and the unmanned aerial vehicle, and then, notify the central server that is has synced-up. At step **158**, the packaging system can tell the loading station and the unmanned aerial vehicle the delivery destination of the package.

Subsequently, at step **159**, the packaging system can sync-up with the unmanned aerial vehicle to check a confidence level for delivery of the package based on the package delivery specifications. At step **160**, it can be determined if the confidence level of unmanned aerial vehicle for transporting the package is “+1” based on the package delivery specifications. At step **161**, the packaging system can connect to the central server to confirm that the unmanned aerial is confident in delivery of the package. At step **162**, the central server can confirm the packaging system inside the distribution center may proceed. At step **163**, the central server can instruct a mechanism of the packaging system to autonomously move the package onto the conveyer belt. At step **164**, the packaging system can use a robotic arm or another form of autonomy to select the next package for delivery. At step **165**, the robotic arm can transport the package to a weighing station.

Upon placement of the package on the weighing station, at step **166**, the weighing station can check the weight of the package. After doing so, at step **167**, the weighing station can notify the loading station, the unmanned aerial vehicle, and the central server of the weight of the package. At step **168**, the weighing station can sync-up with the unmanned aerial vehicle to check its confidence level for delivering the package. At step **169**, the weighing station can confirm that the unmanned aerial vehicle has a confidence level of “+1” (meaning that it is confidence in delivery of the package). At step **170**, the package can then board a conveyer belt for transportation to the loading pad. Upon placement on the conveyer belt, at step **171**, the conveyer belt can connect to the central server to inform that the package is headed towards the conveyer belt. At step **172**, the conveyer belt can double check the package delivery time with the package and notify the central server of such information. At step **173**, the conveyor belt can check where the package is being delivered and notify the central server. At step **174**, the package can then reach the loading station. Lastly, at step **175**, the packaging system and loading pad can connect to the central server when the package and unmanned aerial vehicle meet, as will discussed in more detail below.

Referring back to FIG. 1, as discussed above the loading station **104** can be configured to receive the unmanned aerial vehicle **107** from the landing station **101** and to receive the package from the packaging system **145**. As also discussed above, the packaging system **145** can send an appropriate package for the unmanned aerial to deliver to a delivery destination based on one or more properties of the package and one or more capabilities of the unmanned aerial vehicle **107**. As such, the unmanned aerial vehicle **107** will meet, and attach to, the appropriate package to be delivered to the delivery destination at the loading station **104**.

11

Alternatively, the loading station **104** can be configured to hold and maintain a plurality of packages. As such, when the unmanned aerial vehicle **107** arrives at the loading station **104**, the landing station **104** can determine an appropriate package based on one or more properties of each package and one or more capabilities of the unmanned aerial vehicle **107**. After determining the appropriate package, the unmanned aerial vehicle **107** can be instructed to attach to the package.

Referring now to FIG. 6, an exemplary loading station **104** receiving and holding a plurality of packages is illustrated. As such, the loading station **104** may be a container. The container may have a trap door **177** for the unmanned aerial vehicle to land, a rotating carousel **180** having a plurality of shelves configured to each hold a package, and/or a swivel (not illustrated) to orient the unmanned aerial vehicle **107** to pick-up and attach to the package. The trap door **177** can be configured to open and sized such that a portion of the unmanned aerial vehicle **107** utilized may enter into the container and grab, and attach to, the package inside the container. The rotating carousel **180** may be placed such that it may rotate and place each shelf directly beneath the trap door **177**. This can allow the portion a portion of the unmanned aerial vehicle **107** utilized to grab, and attach to, the package to enter the container and have direct access to the package placed on the shelf directly beneath the trap door. This can also allow the loading station **104**, the central server **106**, and/or the packaging system **145** to select the appropriate package for the unmanned aerial vehicle **107** located on top of the loading station **104**.

Moreover, the loading station **104** can include a first opening **248** and/or a second opening **249**. The first opening **248** can permit the third transportation mechanism **176** to direct to a shelf of the rotating carousel **180**. To do so, the loading station **104** may include a first transportation mechanism **178** extending from the third transportation mechanism **176** to a shelf of the rotating carousel **180**. As to the second opening **249**, it can permit the rotating carousel to get rid of any unwanted packages. To do so, the loading station may include a second transportation mechanism **179** extending from a shelf of the rotating carousel **180**. The first and second transportation mechanisms **178**, **179** can each include a plurality of rollers or a conveyer belt. According to an embodiment, the first transportation mechanism **178** includes a conveyer belt, and the second transportation mechanism **179** includes a plurality of conveyer belts.

Referring now to FIG. 7, an exemplary flowchart illustrating communication between various components of the system **101** for managing selection of a package by an unmanned aerial vehicle **107** at the loading station **104** (each shown in FIG. 1) is depicted. At step **182**, it can be determined if an unmanned aerial vehicle has reached a loading station. Thereafter, at step **183**, the unmanned aerial vehicle and the loading station can each notify the central server if the unmanned aerial vehicle has reached the loading station. At step **184**, the central server can confirm that the loading station may proceed with the loading process. At step **185**, the loading station can check the unmanned aerial vehicles capabilities and notify the central server of such capabilities. At step **186**, the loading station can distinguish what type package (e.g., size, dimension, and weight) available for delivery is compatible to the specific unmanned aerial vehicle. At step **187**, the loading station and the packaging system inside the distribution center can notify the central server of the selected unmanned aerial vehicle.

Subsequently, at step **188**, the loading station can check with the computer inside the distribution center to determine

12

when the package should be delivered and notifies the central server of such information. At step **189**, the loading station can check with the packaging system for where the package is being delivered and notifies the central server of such information. At step **190**, the loading station can check the unmanned aerial's confidence level for delivering the package (e.g., "-1," "0," or "+1").

As described in step **191**, if it is determined the confidence level for the unmanned aerial level to deliver the package is "+1," the unmanned aerial can be deemed confident in the delivery of the package. Thereafter, at step **192**, loading station can notify the central server and packaging system that the unmanned aerial vehicle is confident in the delivery of the package, and as such, the package can proceed onto a conveyer belt heading towards loading pad. At step **193**, the conveyer belt can sync-up with the computer inside the distribution center to double check the package details (i.e., size, weight, dimensions). At step **194**, the conveyer belt can also determine a time of delivery and a destination for the package. At step **195**, once the package has reached the loading station, both the conveyer belt and the loading station can notify the central server that the package has reached the loading station.

However, as described in step **194**, if it is determined the confidence level for the unmanned aerial level to deliver the package is "-1" or "0," the unmanned can be deemed not confident in the delivery of the package. As such, at step **197**, the loading station can notify the central server and the computer inside distribution center that the unmanned aerial vehicle is not confident in the delivery of the package and that the computer needs to skip this delivery and come back to it. Subsequently, at step **198**, the package can be flagged for delivery for the next available unmanned aerial vehicle.

Referring now to FIG. 8, an exemplary flowchart illustrating communication between various components of the system **101** when a package and an unmanned aerial vehicle **107** meet at a loading station **104** (each shown in FIG. 1) is depicted. First, at step **199**, a conveyer belt—transporting the package to the loading station—can notify a central server, once the package has reached a stopping point inside the loading pad directly under the unmanned aerial vehicle and trap door. At step **200**, the package can now reside under the unmanned aerial vehicle inside the loading station. Subsequently, at step **201**, the package, the unmanned aerial vehicle, and the loading station can together notify the central server that the package is currently under the unmanned aerial vehicle. At step **202**, the trap door—under the drone and on top of the load pad—can open and expose the top of the package. At step **203**, the trap door can send a signal to the loading pad that it has opened and to notify the central server. At step **204**, the central server can then send a signal for the unmanned aerial vehicle and the loading station to proceed in loading the package.

In doing so, thereafter, at step **205**, the unmanned aerial vehicle can then lower its crane and attach itself to the exposed side of the package. At step **206**, once the crane of the unmanned aerial vehicle meets the package, the unmanned aerial vehicle can notify the central server. At step **207**, the central server can then signal the unmanned aerial vehicle to proceed with loading the package. At step **208**, the unmanned aerial vehicle can reel in the crane and the attached package, and then, signal to the central server once the package is flush with the underside of the unmanned aerial vehicle. At step **209**, the central server can then respond by telling the unmanned aerial vehicle it is ready to move to the launch pad. At step **210**, the swivel—located on top of the loading station—can turn to direct the unmanned

13

aerial vehicle and the package to a conveyer belt headed towards the launching station.

Thereafter, at step **211**, before the unmanned air vehicle and the attached package boards the conveyer belt, the swivel can notify the central server and wait to proceed to the conveyer belt. At step **212**, the central server can then notify the unmanned aerial vehicle with the attached package to proceed onto the conveyer belt. At step **213**, the unmanned aerial vehicle and the package can board the conveyer belt to head towards the launching station. At step **214**, the conveyer belt can check to make sure the package is secured to the drone and notify the central server of such. At step **215**, the conveyer belt can also double check the destination information and delivery time of the package and notify such to the central server. Lastly, at step **216**, the unmanned aerial vehicle with the attached package can reach the launching station.

Referring back to FIG. **1**, the launching station **105** can be connected to the loading station **104** by a fourth transportation mechanism **181**. As such, the fourth transportation mechanism **181** can transport the unmanned aerial vehicle **107** and the package to the launching station **105**. While being transported, the fourth transportation mechanism **181** can check the attachment of the package to the unmanned aerial vehicle. As such, upon arrival at the launching station **105**, the launching station can check a confidence level for the unmanned aerial vehicle **107** to deliver the package, which can be done in the same manner as discussed above. Once the confidence level is confirmed, the launching station **105** can include a swivel to direct the unmanned aerial vehicle **107** towards its route and permit the unmanned aerial vehicle **107** to depart.

Referring now to FIG. **9**, an exemplary flowchart illustrating communication between various components of the system **100** when a package reaches a loading station **104** (each shown in FIG. **1**) is depicted. Beginning at step **217**, once the unmanned aerial vehicle and the attached package reaches the launching station, the conveyer belt can notify the central server. At step **218**, the launching station can notify the central server that the unmanned aerial vehicle and the attached package has reached the launching station and wait to proceed. As such, at step **219**, the central server can signal the launching station and unmanned aerial vehicle to proceed with the launch.

Prior to launching the unmanned aerial vehicle, at step **220**, the launching station can sync-up with the unmanned aerial vehicle and check a confidence level of the unmanned aerial vehicle in the delivery of the package to the destination. At step **221**, the unmanned aerial vehicle can send its confidence level for delivering the package to the destination to the launching station. At step **222**, the launching station can sync-up with the unmanned aerial vehicle and check its confidence in launching and delivery of the package to the destination. At step **223**, the unmanned aerial vehicle can respond with confidence in launching and delivery of the package to the destination. At step **224**, the launching station can signal to the central server that the unmanned aerial vehicle is now ready for launch. At step **225**, the central server can then notify any surrounding computers that the unmanned aerial vehicle is read ready for launch and deliver.

Once the central server gets approval, at step **226**, the central server can notify the launching station that the unmanned aerial vehicle is cleared of any incoming unmanned aerial vehicle and ready for launch. At step **227**, the launching station can notify the unmanned aerial vehicle that it is cleared for take-off. At step **228**, the unmanned aerial vehicle can signal the launching station and the central

14

server that it is preparing for launch. Lastly, at step **229**, the unmanned aerial vehicle can lift-off, and the launching station can signal to the central server that the unmanned aerial vehicle has lifted off and is proceeding with delivery of the package.

Referring now to FIG. **10**, an exemplary unmanned aerial vehicle port **250** that can be utilize in accordance with embodiments of the present invention is illustrated. The port **250** can belong to a distribution center and/or local store. As such, the port **250** can include a plurality of stations **251-254**. The stations **251-254** can be of the same or different. For example, one station **251** can be a "Refueling Station" that is used for refueling unmanned aerial vehicle ports. Another station **252** can be a "Returning" station used for unmanned aerial vehicles which return from delivery. Additional stations **253, 254** can be "Delivery" stations and used in accordance with embodiment of the invention discussed above. Moreover, the stations **251-254** can have a location outside of the port **250** for the unmanned aerial vehicles to land thereon prior to transportation to their respective station.

Referring now to FIG. **11**, an exemplary system for simultaneously receiving multiple packages **230, 231** at different loading stations **231, 232** in accordance with embodiments of the present invention is illustrated. The packages **230, 231** can be place on different transportation mechanisms **234, 235** which connect to separate loading stations **231, 232**. The transportation mechanism **234, 235** can connect the same or different identifying system (not illustrated) as discussed above with respect to FIG. **1**. Along these lines, the transportation mechanisms **234, 235** can includes rollers and/or a conveyer belt. Moreover, the loading stations **232, 233** can operate the same as discussed above with respect to FIG. **1**. This can allow unmanned aerial vehicles **236, 237** to select and attach to packages in the loading stations **231, 232** in the same manner as discussed above with respect to FIG. **1**.

Referring now to FIG. **12**, an exemplary method for controlling an unmanned aerial vehicle for delivery of a package to a particular destination that can be utilized in accordance with embodiments of the present invention is illustrated. First, at step **238**, a first confidence level of an unmanned aerial vehicle to land on a landing station is determined at a landing station. Thereafter, at step **239**, based on the confidence level, instructing the unmanned aerial vehicle to land on the landing station. Upon landing on the landing station, at step **240**, determining, at said landing station, a second confidence level of the unmanned aerial vehicle for maintenance of the unmanned aerial vehicle. Thereafter, at step **241**, based on the second confidence level, transporting the unmanned aerial vehicle to the loading station. Subsequently, at step **242**, at the packaging system, identifying a package for delivery. Upon doing so, at step **243**, determining a third confidence level of the unmanned aerial vehicle for delivery of the package. At step **244**, based on the third confidence, transporting the package to the loading station. After reaching the loading station, at step **245**, the unmanned aerial vehicle can be instructed to select, and attach to, the package. At step **246**, the unmanned aerial vehicle and the attached package can be transported to a launching station. After reaching the launching station, at step **247**, the unmanned aerial vehicle and the package can launch to the selected destination.

Referring now to FIG. **13**, a schematic diagram of an exemplary server **261** that may be utilized in accordance with the present invention is illustrated. The exemplary server **261** includes a communication device **262**, a proces-

15

sor **263**, and a data storage or memory component **263**. The processor **263** is in communication with both the communication device **262** and the memory component **264**. The communication device **262** may be configured to communicate information via a communication channel, wired or wireless, to electronically transmit and receive digital data related to the functions discussed herein. The communication device **262** may also be used to communicate, for example, with one or more human readable display devices, such as, an LCD panel, an LED display or other display device or printer. The memory component **264** may include any appropriate information storage device, including combinations of magnetic storage devices (e.g., magnetic tape, radio frequency tags, and hard disk drives), optical storage devices, computer readable media, and/or semiconductor memory devices such as Random Access Memory (RAM) devices and Read-Only Memory (ROM) devices. The memory component **264** may store the program **265** for controlling the processor **263**. The processor **263** performs instructions of the program **265**, and thereby operates in accordance with the present invention.

The memory component **263** may also store and send all or some of the information sent to the processor **263** in a plurality of modules **266**, **267**. As such, the module **266**, **267** may each contain data for each of the stations/systems discussed above. This can improve the logic and processing speed of the server **261** in coordinating unmanned aerial vehicles for delivery of one or more packages, as discussed in detail above.

Communication device **262** may include an input device including any mechanism or combination of mechanisms that permit an operator to input information to communication device **262**, such as a keyboard, a mouse, a touch sensitive display device, a microphone, a pen-based pointing device, a biometric input device, and/or a voice recognition device. Communication device **262** may include an output device that can include any mechanism or combination of mechanisms that outputs information to the operator, including a display, a printer, a speaker, etc. Use of language such as “at least one of X, Y, and Z” or “at least one or more of X, Y, or Z” are intended to convey a single item (just X, or just Y, or just Z) or multiple items (i.e., {X and Y}, {Y and Z}, or {X, Y, and Z}). “At least one of” is not intended to convey a requirement that each possible item must be present.

The various embodiments described above are provided by way of illustration only and should not be construed to limit the scope of the disclosure. Various modifications and changes may be made to the principles described herein without following the example embodiments and applications illustrated and described herein, and without departing from the spirit and scope of the disclosure.

We claim:

1. A system for managing unmanned aerial vehicles, comprising:
 - an unmanned aerial vehicle;
 - a landing station for said unmanned aerial vehicle to land thereon; and
 - a loading station configured to receive a package and said unmanned aerial vehicle,
 wherein said unmanned aerial vehicle is stationed away from said landing station and said loading station, wherein said unmanned aerial vehicle is in communication with said landing station and configured to:
 - determine a first confidence level for landing on said landing station,

16

- travel, based on said first confidence level, to said landing station, and
- determine a second confidence level for delivering said package to a destination, and
- wherein said loading station is in communication with said unmanned aerial vehicle and configured to:
 - receive said second confidence level to deliver said package to said destination from said unmanned aerial vehicle, and
 - confirm, based on said second confidence level, said unmanned aerial vehicle is capable of delivering said package to said destination.
- 2. The system of claim 1, wherein said unmanned aerial vehicle is configured to determine said second confidence level after being transported to said landing station.
- 3. The system of claim 1, wherein said loading station is configured to determine if said package is compatible with said unmanned aerial vehicle.
- 4. The system of claim 1, additionally comprising:
 - a central server in communication with said landing station and loading station,
 - wherein said central server is configured to:
 - monitor a location and status of said unmanned aerial vehicle and said package in said system, and
 - control transportation of said unmanned aerial vehicle and said package within said system.
- 5. The system of claim 4, additionally comprising:
 - a maintenance station for maintaining operation of said unmanned aerial vehicle,
 - wherein the maintenance station is in communication with said landing station and said central server,
 - wherein said maintenance station is configured to receive said unmanned aerial vehicle if said first confidence level is below a predefined threshold.
- 6. The system of claim 5, additionally comprising:
 - a first conveyor belt configured to transport said unmanned aerial vehicle to said maintenance station; and
 - a second conveyor belt configured to transport said unmanned aerial vehicle to said loading station,
 - wherein said first conveyor belt comprises first sensors which check maintenance of one or more components of the unmanned aerial vehicle, and
 - wherein the second conveyor belt comprises second sensors which check one or more capabilities of the unmanned aerial vehicle.
- 7. The system of claim 5, wherein the landing station comprises a rotating swivel attached to the landing station, the rotating swivel configured to rotate and align said unmanned aerial vehicle with said maintenance station or said loading station.
- 8. The system of claim 4, additionally comprising:
 - a computer for a distribution center;
 - a packaging system for a distribution center and comprising a storage for said package,
 - wherein said packaging system is in communication with the computer to determine one or more packages to be delivered,
 - wherein the packaging system is in communication with the central server to send said package to be delivered by said unmanned aerial vehicle.
- 9. The system of claim 8, additionally comprising:
 - an identifying system in communication with said packaging system and configured to identify one or more properties of the package,
 - wherein determining said second confidence level is based on said property of said package.

17

10. The system of claim 8, wherein determining said second confidence level is further based on one or more properties of said unmanned aerial vehicle.

11. The system of claim 1, additionally comprising:

a launch station separate from said landing station and said loading station, wherein said unmanned aerial vehicle departs from said launch station with said package to said destination.

12. The system of claim 11, wherein said loading station configured to receive said unmanned aerial vehicle from said landing station and to receive said package from a packaging system, wherein said unmanned aerial vehicle is configured to select said package at said loading station.

13. The system of claim 12, additionally comprising:

wherein said loading station comprises a rotating carousel and a trap door, the rotating carousel having a plurality of shelves configured to hold a package and be placed directly beneath the trap door, the trap door configured to open to permit said unmanned aerial vehicle to attach to said package.

14. The system of claim 1, wherein the first confidence level is -1, 0, or 1, wherein the first confidence level being -1 or 0 indicates that said unmanned aerial vehicle is not confident to land or deliver said package, and the first confidence level of +1 indicates that said unmanned aerial vehicle is confident to land or deliver said package.

15. A system for managing unmanned aerial vehicles, comprising:

an unmanned aerial vehicle;

a landing station for said unmanned aerial vehicle to land thereon,

a maintenance station in communication with said landing station and configured to perform maintenance on said unmanned aerial vehicle;

a packaging system comprising a storage for storing a plurality of packages; and

a loading station configured to receive said unmanned aerial vehicle from said landing station and to receive a package from said packaging system, said loading station in communication with said packaging system, wherein unmanned aerial vehicle is configured to:

determine a first confidence level for landing on said landing station, and

travel, based on said first confidence level, to said landing station or said maintenance station,

wherein said loading station is configured to:

receive, from said landing station, said unmanned aerial vehicle,

receive, from said packaging system, said package,

18

determine a second confidence level for said unmanned aerial vehicle to deliver said package,

select, based on said second confidence level, said package for said unmanned aerial vehicle, and

instruct, based on said second confidence level, and unmanned aerial vehicle to select and attach to said package for delivery to a destination.

16. The system of claim 15, additionally comprising:

a maintenance station for maintaining operation of said unmanned aerial vehicle,

wherein the maintenance station is in communication with said landing station,

wherein said maintenance station is configured to receive said unmanned aerial vehicle if said first confidence level is below a predefined threshold.

17. The system of claim 16, wherein the unmanned aerial vehicle is configured to receive said package if the first confidence level is above the predefined threshold.

18. The system of claim 15, wherein the loading station comprises a plurality of packages including said package, said plurality of packages being stored on a plurality of shelves within the loading station, each shelf within the plurality of shelves holding a package from the plurality of packages.

19. A method for managing unmanned aerial vehicles, comprising:

determining, at a landing station, a first confidence level of an unmanned aerial vehicle to land on said landing station;

instructing, based on said first confidence level, said unmanned aerial vehicle to land on said landing station;

determining, at said landing station, a second confidence level of said unmanned aerial vehicle for maintenance;

transporting, based on said second confidence level, said unmanned aerial vehicle to a loading station;

identifying, at packaging system, a package for delivery;

determining, at said packaging system, a third confidence level of said unmanned aerial vehicle for delivery of said package;

transporting, based on said third confidence level, said package to said loading station;

instructing, at said loading station, said unmanned aerial vehicle to select and attach to said package;

transporting said unmanned aerial vehicle and said package to a launching station; and

launching, at said launching station, said unmanned aerial vehicle and said package to said destination.
